

WindowHelper

For MapInfo Pro

November 2022

Installation

WindowHelper is to be downloaded from the MapInfo Marketplace.

This distribution is automated so that you only have to click a button to get the add-in installed and loaded into MapInfo Pro.

If any updates to the tool gets published, you will see the small **Notification** symbol in the lower right corner of the MapInfo Pro window turn red. Double-click on the symbol to open the **Notification** window and from here access the updates from the MapInfo Marketplace where you easily can install the updates.

Please note that WindowHelper requires MapInfo Pro v17.0.3 or newer to work.

About WindowHelper

WindowHelper is a tool that adds additional features to MapInfo Pro which helps you while working in especially map and browser windows.

WindowHelper is designed for the new ribbon-based interface of MapInfo Pro 64 bit.

WindowHelper is consider a new tool even though it has been built on top of the earlier WindowHelper 2.1. But moving the tool to the 64-bit has made big parts of the tool obsolete as these features now are supported directly in the MapInfo Pro interface.

To get the most out of this tool it is recommended that you set it to Autoload.

The features of this tool have been made in response to requests from customers.

If you have any requests or feedback on the WindowHelper, please send your feedback through this article on the MapInfo Pro Community:

Features of WindowHelper

When you run the WindowHelper tool, it will place buttons on the ribbon, menu items in a number of context menus and embed itself in the Tools window.

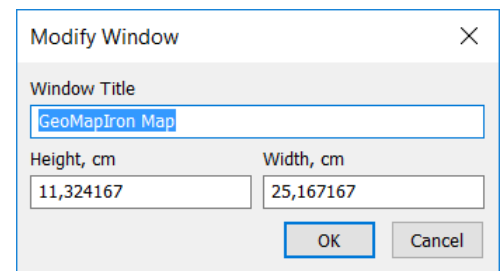

The *WindowHelper* tool embeds itself in a number of places. Some features are placed directly on tabs of the ribbon, and you will find many feature in context menu/right click menus in a number of places.

Modify Window

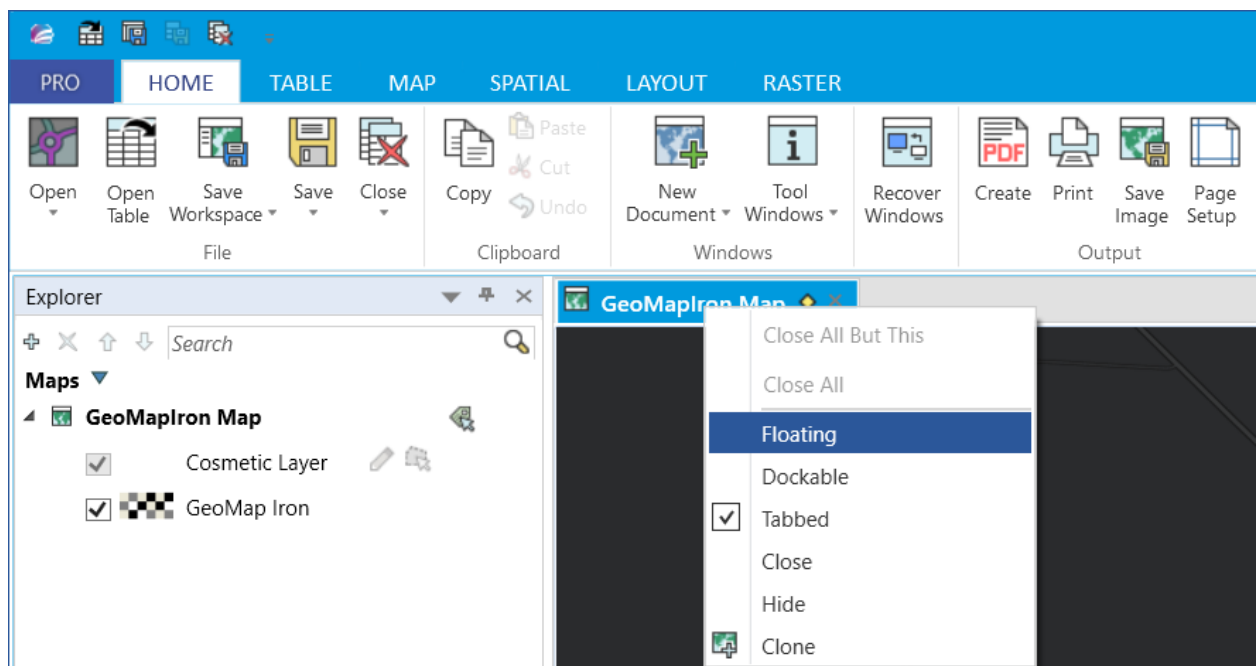

The *Modify Window* option can be found on the *HOME* tab in the *Windows* group. It lets you specify the floating size of document window. This is useful if you need to export your map window to an image of a certain size.

The *Modify Window* dialog lets you specify a title for the window and set a height and width of the window using the current paper units.

Click OK to apply the values entered in the dialog.

If your window is not floating, you will not see the size change until you make the window floating. You can do this by right clicking on the tab of the window and select *Floating* from the context menu.

Creating Map Extent

You can use the WindowHelper tool to create the extent from one map window in another map window. This can be used for printing or simply for positioning your detailed map in an overview map.

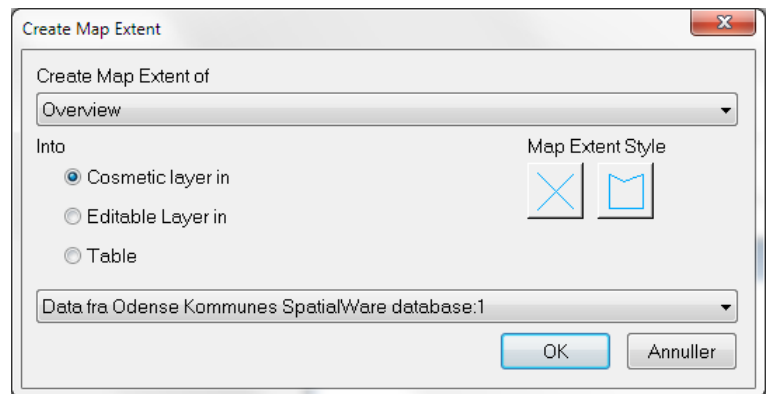

You can also create the map extent of the map window in the window itself. This can be useful if you need to find objects within the current map extent.

On the *MAP* tab in the group *Options*, click on *Map Extent* to start the process. You can also access this feature via the right click menu in the map window.

In the dialog *Create Map Extent* you can now pick the window which map extent you want to create.

You can choose three ways of storing the map extent:

- The cosmetic layer of a map
- The editable layer of a map
- A table

If you pick 1 or 2, you must also pick what map window to store the map extent into. If you pick the 3rd option you must pick what table to store the map extent into.

In the dialog, you can also change the style for the map extent created. The style will be written to the configuration file and used again next time you create a map extent.

Show Info on Selection

The feature has been moved into WindowHelper from a stand-alone tool called InfoSelHandler.

When activated, the tool shows the attributes of the selected (and deselected) record in the Info window.

You can turn the tool on and off via the *Show Info* control in the *Options* group on the *MAP* tab.

This has been enhanced to also show the number of selected records in the statusbar. It shows the number of selected records and the total number of records in the base table. This is always active also when Show Info on Selection has been deactivated.

Locate File in Windows Explorer

In the right click menu of the *Tables* window and the right click menu of the layers in the *Layers* and the *Explorer* window you find this menu item, which lets you locate and select the file of a table/layer in Windows Explorer.

This feature works on one selected table or layer.

If you have selected a raster layer/table, you will be asked if you want to locate the tab file or the raster file.

This has been disabled if you are using MapInfo Pro v2021 or newer where this feature has been built into the core product.

Browse in floating Window

The *Browse in floating Window* lets you browse a table in a floating browser window instead of a tabbed browser window which is the default behavior.

You can find this option on the context menu of the tables in the *Table List* and on the *TABLE* tab next to *New Browser*.

You can also use the shortcut *Ctrl+Shift+F4*.

Save Window to Workspace

The feature *Save Window to Workspace* can be found on the *HOME* tab in the *Output* group. It save the currently active window to a workspace file without saving any of the *Open Table* statements.

It can be used for creating templates for layouts or even map windows. It's up to you as a user to make sure that the tables used in the window are open when you reopen this workspace.

Open File In Favorite Text Editor

In the right click menu of the *Tables* window and the right click menu of the layers in the *Layers* and the *Explorer* window you find this menu item, which lets you open the tab file of a table/layer in your preferred text editor, for example Notepad.

This feature works on one selected table or layer.

This gives you quick access to the content of the tab file and an overview of the table structure as well as the metadata of the tab file.

Close Table

In the right click menu of the layers in the *Layers* and the *Explorer* window you find the *Close table* menu item, that makes it easy to close the table for a specific layer.

This feature works on one selected layer.

Notice that when you close the table thru the layer, all windows only showing this table and queries based on this table are also closed.

Set Default View/Set Default View on All Layers

You will find this menu item in the right click menu of the Maps and of the Layers in the Layer Control.

If you use the menu item from the Maps right click menu, the default view will be set on all layers of the map that support this.

If you use the menu item from the Layers, you will set the default view of one layer at a time.

The default view is the zoom and center of a table used when the table is open as the first table in a new map window.

Static Theme

MapInfo Pro allows you to store the styling for a layer in different way: at an object level on the table, as a layer override and as a theme.

There are times where you might want to switch from the object level to a theme. This is where *Static Theme* can help you.

It lets you create a theme based on values in a selected column and the style matching one record with this value. It will of course work best if all your objects with the same value have the same styling.

You can find *Static Theme* on the *MAP* tab right next to *Add Theme*.

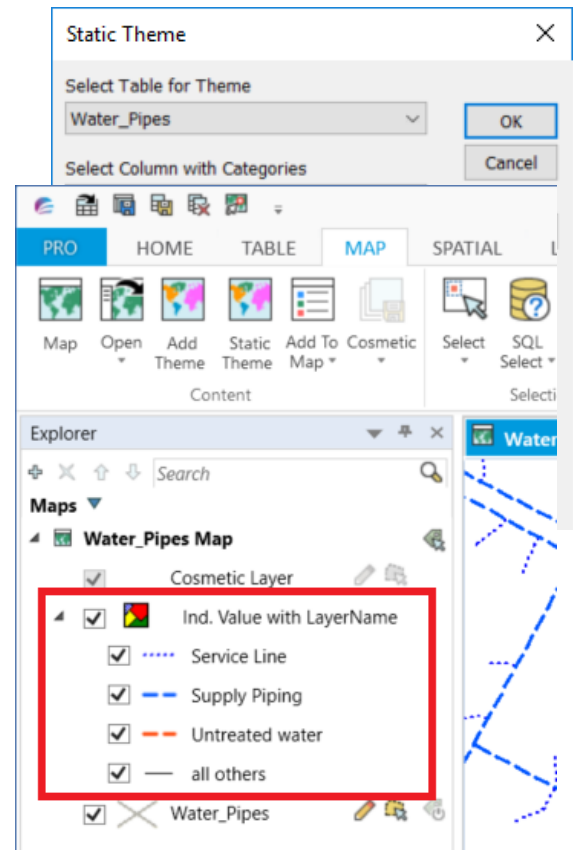

First, you need to select the table you want to create a Static Theme on and then the column holding the values.

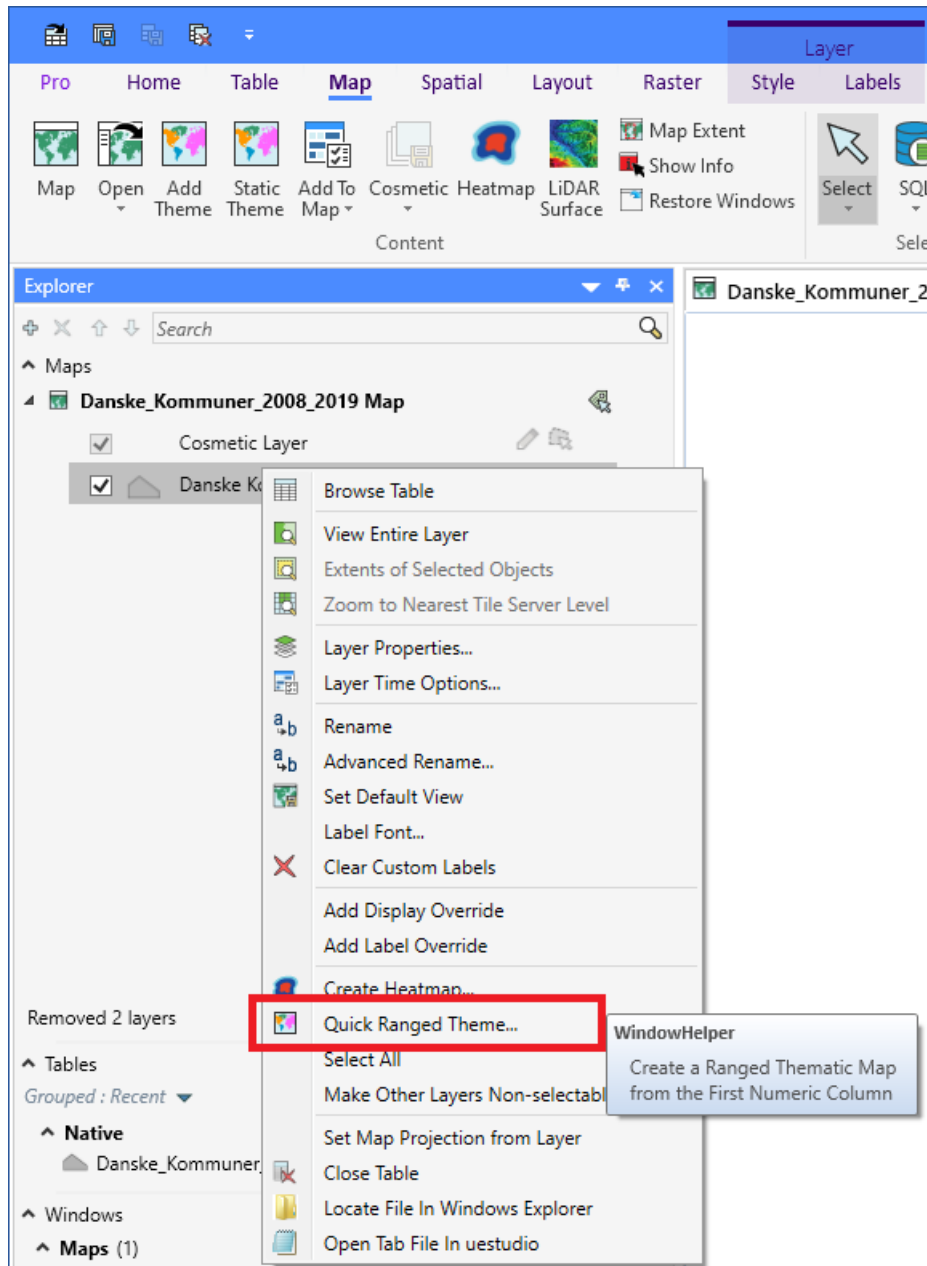

WindowHelper will now create a theme based on the values in the column selected and the style of one of the records with the specific value.

The result can be seen as a new theme in the *Layer List*.

One use case for this is when you want to publish your table to Spectrum Spatial Analyst. If you have a theme on your layer, the legend in Spectrum Spatial Analyst will look a lot better than if the legend is created based on the styling from the objects in the table.

Quick Ranged Theme

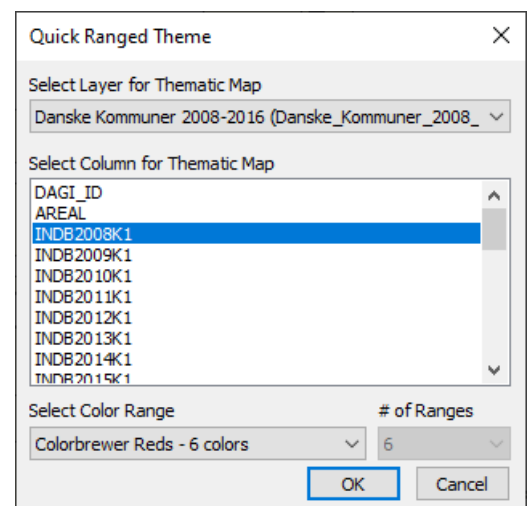

From the right-click menu on a layer, you can now access *Quick Ranged Theme...* which allows you to create a ranged thematic in a few clicks.

From the *Quick Ranged Theme* dialog, you can select the layer and the column to use. Notice that the layer has been preselected to be the layer you right clicked on in the *Layer List*.

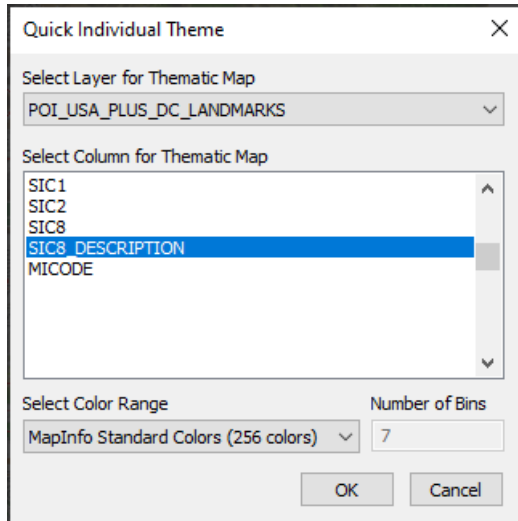

From the *Select Color Range* list, you can select one of multiple color ranges to use, and *# of Ranges* can allow you to set the number of ranges in your thematic map.

The color ranges are read from a configuration file, *QuickThematic.ini*, stored in the folder where *WindowHelper* is installed. Some ranges just defined a start and an end color. For these you can specify the number of ranges. Others define a fixed number of colors. For these you can't define

the ranges. But remember you can now quickly modify your thematic map using the *Theme* tab.

Quick Individual Theme

From the right-click menu on a layer, you can now access *Quick Individual Theme...* which allows you to create a individual thematic in a few clicks.

From the *Quick Individual Theme* dialog, you can select the layer and the column to use. Notice that the layer has been preselected to be the layer you right clicked on in the *Layer List*.

From the *Select Color Range* list, you can select one of multiple color ranges to use, and *# of Bins* tells you how many different values the selected column holds. This will equal to the number of bins in your individual thematic map.

If there are more bins than colors, each color might appear multiple times.

The color ranges are read from a configuration file, *QuickThematic.ini*, stored in the folder where *WindowHelper* is installed. Some ranges just defined a start and an end color. For these MapInfo Pro will calculate a total of 24 colors spread between the input colors. Others define a fixed number of colors. But remember you can now quickly modify your thematic map using the *Theme* tab once it has been created.

Currently, the default styles for the themes are hardcoded. Regions will be shown with a full hatch pattern and no border line. Points will be shown with a cross symbol, and lines will be shown with a full line style.

Copy and Paste Layer Properties

From the context menu of the layers, you can copy the layer properties of a selected layer. Once you have copied these, you will be able to paste these onto other layers.

This can help you reuse layer properties from one layer on one or more other layers, or on the same layer in a different map window.

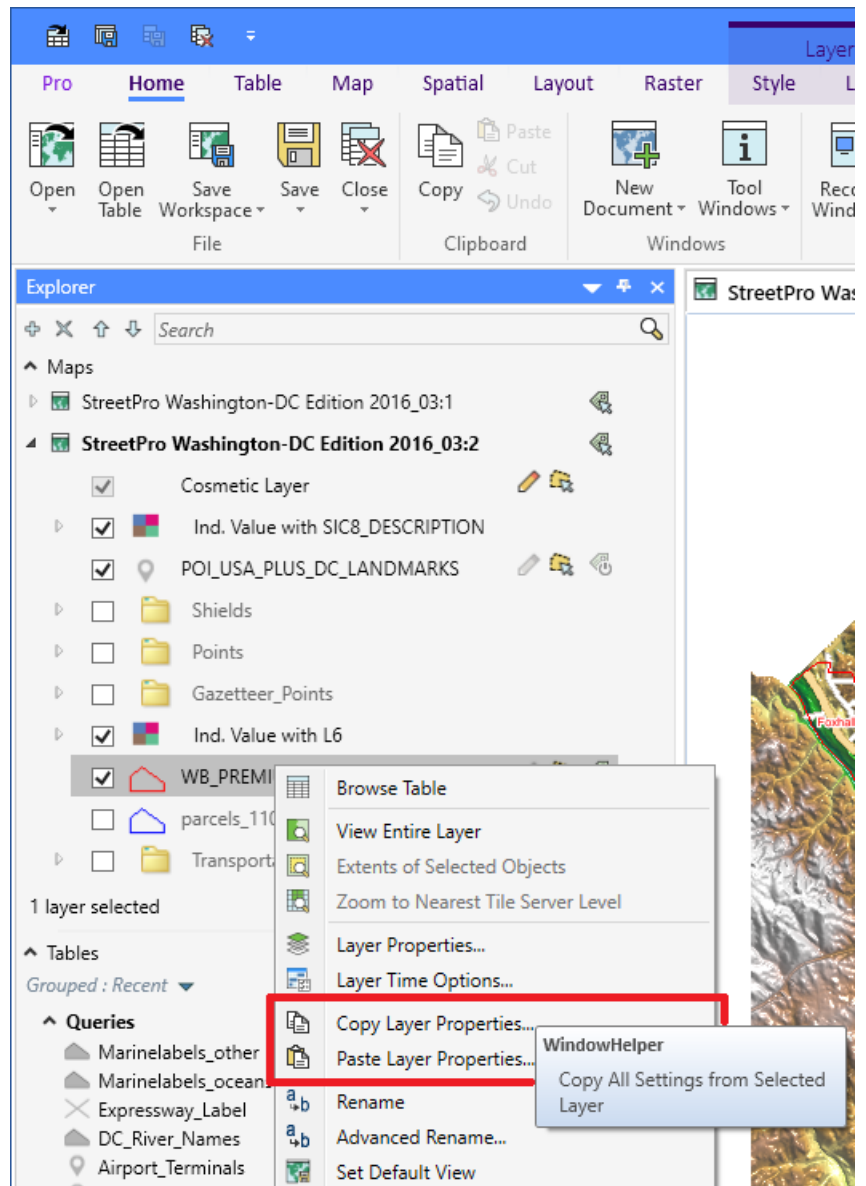

You can paste the copied properties onto most layer types, such as vector and raster layers.

WindowHelper currently doesn't support copying from and pasting to cosmetic layers and thematic layers.

When you paste to a different layer type, WindowHelper will ensure that only properties supported by the layer will get pasted. You will for example not be able to paste global styles from a vector layer onto a raster layer.

For label expression, WindowHelper will try to validate that the column exists. If it doesn't, it will use the first column of the layer. If you have used a label expression, WindowHelper will try to apply this onto the layer. This may however fail if the expression is referring to columns that don't exist on that layer.

Currently only layer styles and label properties are copied and pasted. WindowHelper doesn't copy style overrides, label overrides, hotlink settings, time properties, and filters.

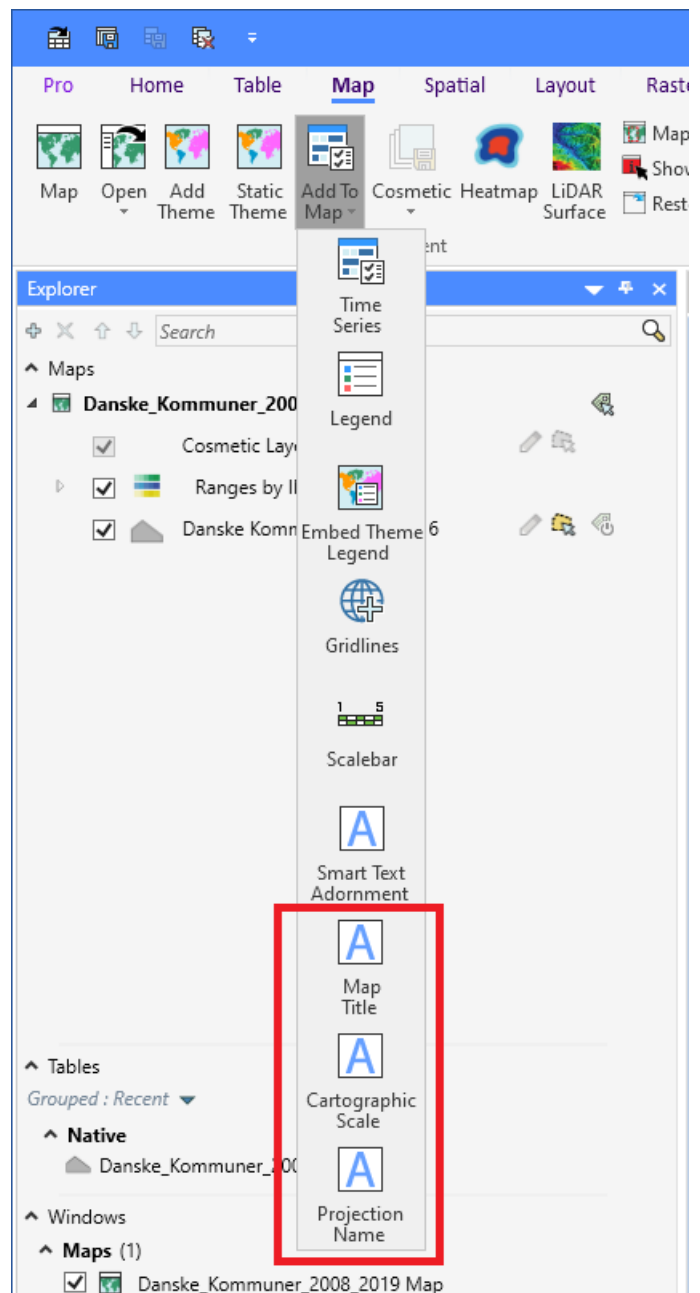

Add Smart Text to map

MapInfo Pro v2021 came with a new capability: Smart Text Annotations for maps.

WindowHelper can help you add a few commonly used annotations to the map with a single click.

From the Add to Map dropdown, you can choose between three options:

- Map Title: This will show the name of the map in the upper left corner of the map window
- Cartographic Scale: This will show the scale in the lower left corner of the map in this form: "1:10,000".
- Projection Name: This will show the name of the projection for the map in the lower right corner of the map.

Restore Closed Windows

On the MAP tab in the group **Options** you also find the feature Restore Windows.

This option lets you restore windows that have been closed during the current session. This can help you recreate a map that you closed by accident.

Click on the *Restore Windows* button and select the window that you want to restore. Then click on Restore. When you have restored all the windows, you want to, close the *Restore Windows* dialog via *Cancel*.

What happens is that WindowHelper takes a snap shot of the window just before the window is being closed. This snap shot is similar to the statement that you will find in a workspace.

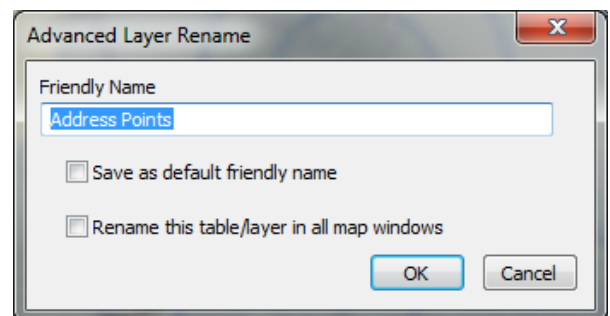

There is however one difference: WindowHelper does not “capture” which tables needs to be open. All it captures is the Window statement. So if you have closed some tables since you closed the window, the restore window might not work.

Advanced Rename Layer

The Advanced Rename Layer feature builds on the feature added with MapInfo Pro 15.0 that lets you give a layer a friendly name.

This feature extends the capability slightly. You will find *Advanced Rename* in the context menu of the Layers in the *Explorer* and then *Layers* window.

When renaming a layer of a base table, you can now also save the friendly name as the default friendly name. This saves the friendly name as the table description to the metadata section of the table and MapInfo Pro can then automatically apply this name when you add the table to a map.

You can also rename the table in other map windows, if it should exist multiple times.

Rename Multiple Layers

Rename Multiple Layer is found in the context menu of the *Map* in the *Explorer* and *Layers* window.

With this feature, you can easily change the friendly name of all the layers in your map.

It will rename the tables to match the file name of the tables. This means that where MapInfo Pro normally would use an underscore instead of a space, you will now see a space and so a nicer looking layer name.

You have a few options when renaming all your layers:

- *Skip Layer with Friendly Name* lets you keep the friendly name of layers that already have been given a different layer name
- *Use Existing Table Description* will check if the table has a description stored in the metadata section. If there is, this description will be used as the friendly name.
- *Save as default friendly name* will save the friendly name used as the table description in the metadata section of the individual tab file.

Pan and Zoom to Selection in Browser Context menu

In the context menu of the Browser window, you can find to options that help you move your map to the currently selected record(s).

AddressKey	ShortName	LongName	MunicipalityCode	StreetCode	StreetName
Ådalsvej 379	Husnr	Husnummer	461	38	Ådalsvej
Ågade 2			461	42	Ågade
Ågade 4				42	Ågade
Ågade 6				42	Ågade
Ågade 8				42	Ågade
Ågade 10				42	Ågade
Ågade 12				42	Ågade
Ågade 14				42	Ågade
Ågade 16				42	Ågade
Ågade 18				42	Ågade
Ågade 18A				42	Ågade
Ågade 20				42	Ågade
Ågade 20A	Husnr	Husnummer	461	42	Ågade

Zoom to Extent of Selection pans and zooms to the extent of the currently selected records in your Map window. This feature supports a selection with more than one record. If you have selected just one point, the map will only pan, not zoom.

Pan to the Selected Record pans your Map window to the centroid of the selected record. The map will not be zoomed. Also note that this feature only support one selected record.

Filter By Cell Value

This feature can be found in two places:

- In the context menu of the browser window
- And in the *Filter* menu in the *Sort and Filter* group on the *TABLE* tab.

The feature gives you are very easy way to filter your browser window using a value in a cell.

Click in the cell with the value that you want to filter the table using. Be aware that the tool by default ignores the top left cell, so avoid using this cell.

Now click on *Filter By Cell Value* in one of the two places.

The browser window will now only show records matching the value you highlighted.

Country	Capital	Continent	Numeric_code	FIPS	ISO_2	ISO_3	Pop_1994	P
Aruba	Oranjestad	North America	533	AA	AW	ABW	66.687	
Antigua and Barbuda	St. Johns	North America	28	AC	AG	ATG	64.794	
United Arab Emirates	Abu Dhabi	Asia	784	AE	AE	ARE	862.000	
Afghanistan	Kabul	Asia				AFG	15.513.267	
Algeria	Algiers	Africa				DZA	22.600.957	
Azerbaijan	Baku	Europe				AZE	7.021.178	
Albania	Tirane	Europe						
Armenia	Yerevan	Europe						
Andorra	Andorra La Vella	Europe						
Angola	Luanda	Africa						
American Samoa	Pago Pago	Oceania						

Group By Current Column

This feature can be found in the context menu of the browser window.

Click in a cell in a Browser window and then right-click to access *Group By Current Column*.

The screenshot shows the 'Addresses Browser' window with a table of addresses. The columns are: LongName, MunicipalityCode, StreetCode, StreetName, HouseNo, NouseNoLitra, Visibility, AddressType, and Direction. A right-click context menu is open over the 'StreetName' column, with the option 'Group By Current Column' highlighted. A 'WindowHelper' tooltip is displayed, stating: 'Run a Group By Query on the currently selected column.'

LongName	MunicipalityCode	StreetCode	StreetName	HouseNo	NouseNoLitra	Visibility	AddressType	Direction
Husnummer	461	11	A.P. Rasmussens Allé	4		Ja		141,4
Husnummer	461	11	A.P. Rasmussens Allé					258,58
Husnummer	461	11	A.P. Rasmussens Allé					139,52
Husnummer	461	11	A.P. Rasmussens Allé					251,9
Husnummer	461	11	A.P. Rasmussens Allé					258,39
Husnummer	461	11	A.P. Rasmussens Allé					258,39
Husnummer	461	11	A.P. Rasmussens Allé					212,94
Husnummer	461	11	A.P. Rasmussens Allé					112,91
Husnummer	461	11	A.P. Rasmussens Allé					112,91
Husnummer	461	11	A.P. Rasmussens Allé					113,48
Husnummer	461	11	A.P. Rasmussens Allé					127,04
Husnummer	461	19	A. Jakobsens Vænge					200
Husnummer	461	19	A. Jakobsens Vænge	16	A	Ja		196,18

As a result, you will get a floating window where the values from the selected column have been grouped and sorted. Next to the values, you can see a count telling you how many times the values appear.

The screenshot shows the 'Addresses_GrpOn_StreetName Browser' window. The table displays the results of a 'Group By' query on the 'StreetName' column. The columns are 'StreetName' and 'NumRecords'.

StreetName	NumRecords
A. Jakobsens Vænge	18
A.P. Rasmussens Allé	11
Aarestrupvej	28
Abels Allé	83
Abigaelsvej	26
Abildhøj	16
Absalonsgade	35

Function List

MapInfo Pro 17.0 has a new function that lets you call/use custom subprocedures and functions in a running MapBasic application from multiple places in MapInfo Pro. You can sue these functions from a label expression, in a SmartText in a Layout, in a SQL Select statement, in an Update Column statement and in multiple other places.

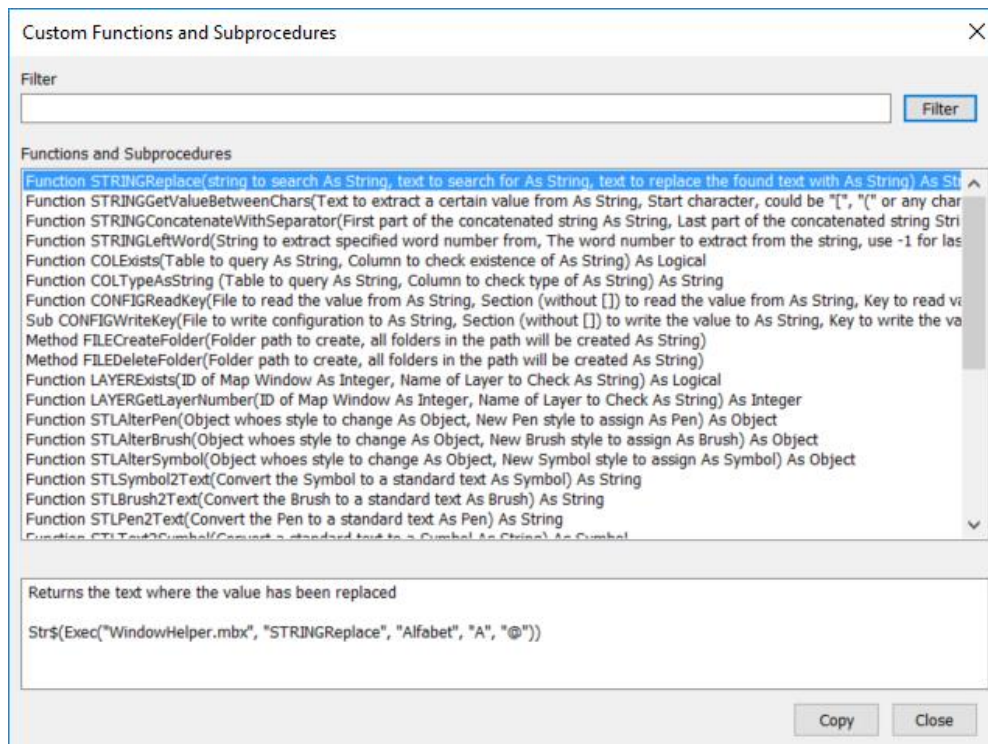

The problem often is to know which functions a MapBasic application provides you access to.

WindowHelper comes with a dialog that lets you view some of the available functions in the tool. You can then quick copy an expression using each function and use these in MapInfo Pro.

You access this list of functions from the context menu of the WindowHelper application in the Tools window, see image under Options further down in this document.

Use the *Filter* option to search for specific functions and click on a function in the list to see a description of the function and an example expression.

Use the *Copy* button or double-click on a function in the list to copy the sample expression to the clipboard.

Published custom MapBasic functions

WindowHelper takes advantage of the new option to publish custom MapBasic functions to the MapInfo Pro interface. Do note that these functions have also been published to the MapInfo Pro interface which makes it even easier to use them. You can see a complete list of functions in the **What's New chapter**.

These functions will appear in the Functions dropdown list in SQL Select, in Update Column and in other Expressions dialog thru out the product.

You can also use these functions from the MapBasic and in workspaces if you are using these to perform automated tasks. Just make sure WindowHelper is running when you want to use the functions.

Currently these functions have been published:

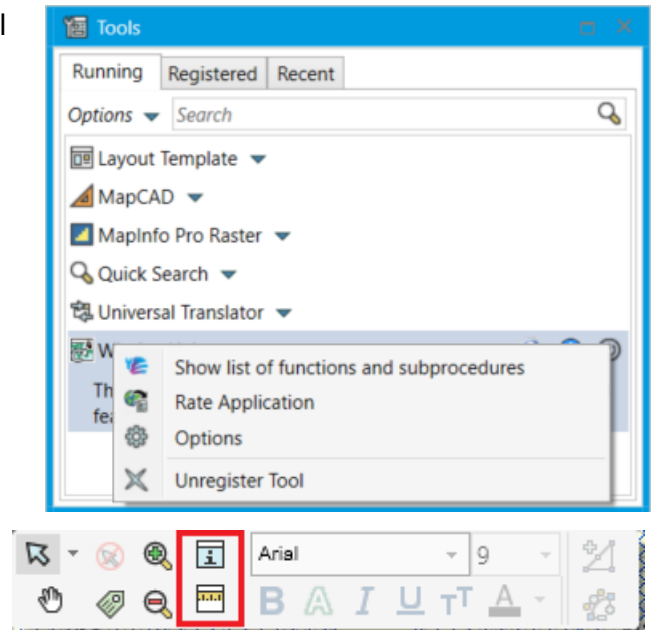

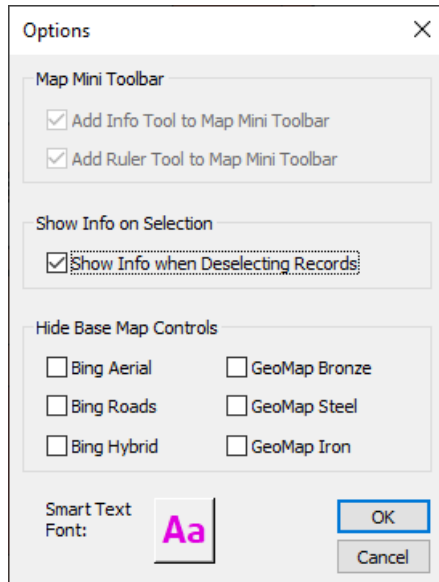

- **WHSetCoordsysUsingTable**(*tableName*)
 - *tableName* is the name of an open table whose coordsys you want WindowHelper to use. This is useful when using some of the spatial functions of WindowHelper such as MAPGetExtent, OBJCartesianCreatePointAlong and more
- **WHSetCoordsysUsingMap**(*windowID*)
 - *windowID* is the ID of the map whose coordsys you want WindowHelper to use. This is useful when using some of the spatial functions of WindowHelper such as MAPGetExtent, OBJCartesianCreatePointAlong and more
- **WHGetSelectionValue**(*recordNo As Integer, columnName As String*)
 - *recordNo* is the record that you want to read the value from
 - *columnName* is the name of the column to read the value from
 - Returns the value from the specified column of the current selection
- **WHGetColumnValue**(*tableName, columnName, recordNo, showError*)
 - *tableName* is the table to read the value from
 - *columnName* is the column to read the value from
 - *recordNo* is the record number to read the value from
 - *showError* specifies if the function should return the error or an empty string when a value can't be read. Set it to 1 to understand why it doesn't return a string in certain cases.
 - Returns the value from the specified column of the specified table
 - Can be useful as a SmartText to read values from a table and add these to the layout
- **WHReplace\$**(*inputString, searchFor, replaceWith*) As String
 - *inputString* is the string, or column name, you want to find a given string in
 - *searchFor* is the string you are searching for
 - *replaceWith* is the string you want to use instead of the *searchFor* string.
 - Returns the *inputString* where the occurrences of *searchFor* have been replaced with *replaceWith*.
- **WHGetValueBetweenChars\$**(*inputString, startChar, endChar*) As String
 - *inputString* is the string, or column name, you want to search
 - *startChar* is the first character you are looking for, for example "{"
 - *endChar* is the end character you are looking for, for example "}"
 - Returns the string between the *startChar* and *endChar* if found, otherwise "".
- **WHConcatenateWithSeparator\$**(*stringFirst, stringLast, stringSeparator*) As String
 - *stringFirst* and *StringLast* are the two strings you want to combine.
 - *stringSeparator* is the string to put between the *stringFirst* and *stringLast*.
 - Returns a string where the two strings have been combined. If none of them are empty string, *stringSeparator* is added in between. If one of them are empty, the other string is returned and the *stringSeparator* is not used.

- **WHLeftWord\$(inputString, wordNumber)** As String
 - *inputString* is the string, or column name, you want to extract a word from
 - *wordNumber* is the word number you want to extract. If you specify -1, it will return the last word
 - Returns the *wordNumber* from the list of in the *inputString* when it is separated by spaces.
- **WHCoulmnExists(tableName, columnName)** As Logical
 - *tableName* is the table to look for the column
 - *columnName* is the column to look for
 - returns true (1) if the specified column is found in the specified table, otherwise it will return false (0).
- **WHColumnTypeAsString(tableName, columnName)** As String
 - *tableName* is the table to look for the column
 - *columnName* is the column to look for
 - returns a string representing the column type, including width. If the table isn't open or the column doesn't exists, an empty string is returned.
- **WHTableIsOpen(tableName)** As String
 - *tableName* is the table to look for
 - returns true (1) if the table is open, otherwise it returns false (0)
- **WHConfigReadKey(fileName, sectionName, keyName)** As String
 - *Filename* is the config file to read a key value from. Use full path
 - *sectionName* is the section to find the key under. Do not include [] around the section name.
 - *keyName* is the key to get the value from.
 - Returns the value assigned to the specified key under the section in the config file.
- **WHConfigWriteKey(fileName, sectionName, keyName, stringValue)**
 - *Filename* is the config file to read a key value from. Use full path
 - *sectionName* is the section to find the key under. Do not include [] around the section name.
 - *keyName* is the key to get the value from.
 - *stringValue* is the value to assign the specified key.
- **WHAlterPen(object, penNew), STLAlterBrush(object, brushNew), WHAlterSymbol(object, symbolNew)**
 - *object* is the object to change. Can also be a spatial column, like OBJ
 - *penNew, brushNew* or *symbolNew* is the new style to apply on the object
 - returns the object with the new styling applied
- **WHSymbol2Text(symbol), STLBrush2Text(brush), STLPen2Text(pen)**
 - *symbol, brush, pen* is the styles you want to have converted into a string representation, like "1,2,255" for a full pattern blue line with a width of 1.
 - returns a string that represents the style.
- **WHText2Symbol(stringSymbol), STLText2Brush(stringBrush), WHText2Pen(stringPen)**
 - *stringSymbol, stringBrush, stringPen* is the string representing the style you want to have converted into a true style.
 - returns the style, pen, symbol or brush, represented by the string entered.
- **WHChangeSymbolColour(symbol, newColorValue)**
 - *symbol* is the symbol that should have a new color assigned
 - *newColorValue* is the new color to assign to the symbol
- **WHObjectReverse(object)**
 - *object*: The line or Polyline you want to reverse the node order of
 - returns the input object with the nodes order reversed.

- **WHCartesianCreatePointAlong**(*object, distance, offset*)
 - *object* is the line/polyline (single segment) you want to create a point along
 - *distance*, is the distance along the line. A negative distance creates the point before the first node.
 - *offset* is the distance perpendicular to the line you want to offset the point. Negative is left, positive is right
 - returns the points along the input line. Set the coordinate system using `WINHSetCoordsysUsingTable` using a projected table.
- **WHDebugEnable**(*enableDebug*)
 - *enableDebug* is a logical value that turns debug on or off
- **WHMapGetExtent**(*windowID*)
 - *windowID* is the ID of the Map window to get the extent of. Can also be `FrontWindow()` for the current active map window.
 - *returns a spatial object representing the extent of the map window.* Set the coordinate system using `WINHSetCoordsysUsingTable` using a table.
- **WHMapGetCoordinate**(*windowID, coordinateType*)
 - *windowID* is the ID of the map you want to get the coordinate from.
 - *coordinateType* is the coordinate you want to retrieve. The value can be one of these: `MINX, MAXX, MINY, MAXY, CENTX, CENTY`
 - returns the coordinate specified from the map. The coordinate will be returned using the current coordinate system of the map.
- **WHRegExReplace**(*inputString, patternString, replaceString*)
 - *inputString* is the input string to search using Regular Expression.
 - *patternString* is the pattern to look for in the input string
 - *replaceString* is the text to replace the pattern with in the input string
 - returns *inputString* where the *patternString* has been replaced with the *replaceString* if match was found.
- **WHRegExIsMatch**(*inputString, patternString*)
 - *inputString* is the input string to search using Regular expression
 - *patternString* is the pattern to search for in the input string
 - *returns true if the pattern was found, otherwise false*
- **WHRegExFirstMatch**(*inputString, patternString*)
 - *inputString* is the input string to search using Regular expression
 - *patternString* is the pattern to search for in the input string
 - returns the first substring from *inputString* that matches the pattern
 - read more about the use of Regular Expressions here: <https://docs.microsoft.com/en-us/dotnet/standard/base-types/regular-expression-language-quick-reference>

Options

If you right click on the WindowHelper tool in the *Tools* window, you can access the options for the tool.

The options lets you specify if you want to add the *Info Tool* and the *Ruler Tool* to the *Map Mini Toolbar*. These have been disabled if you are using MapInfo Pro 17.0 or newer as you can modify the *Map Mini Toolbar* via the *Customize Ribbon* dialog.

We have in certain cases seen issues when the tool shows information about the deselected features. If you start to see misbehaviour, you can turn of the showing of information when deselecting records.

You can also control the visibility of the Base Maps controls that appear on the *Open* dropdowns on the *HOME*, *TABLE* and *MAP* tabs. Check those base map controls that you want to hide from the dropdowns.

And you can set the default font for the Smart Text options that WindowHelper add to the **Add to Map** dropdown.

Improvements to WindowHelper

New features in WindowHelper 3.9.5

Quick Individual Theme allows you to create a individual theme from the layer context menu in very few mouse clicks.

Copy and Paste Layer Properties allows you to copy layer properties from one layer and paste it onto one or more other layers.

Move some controls back to the Options group on the Map tab that mistakenly had been moved to the Content group.

Quick Ranged Theme now also supports query layers.

New features in WindowHelper 3.9.0

Removing command (Find in Folder) that have been added to MapInfo Pro v2021

Images for the ribbon have been made transparent

New options for inserting Smart Texts onto the map window: Window Title, Cartographic Scale and Projection Name.

Quick Ranged Theme allows you to create a ranged theme from the layer context menu in very few mouse clicks.

New features in WindowHelper 3.7.0

Published functions to the MapInfo Pro interface

We have renamed some of the functions publish and remove some functions that were merely added for testing purpose. Some of these have been added to MapInfo Pro v2019.

Renamed functions

- WINHSetCoordsysUsingTable, renamed to WHSetCoordsysUsingTable
- STRINGReplace, renamed to WHReplace\$
- STRINGGetValueBetweenChars, renamed to WHGetValueBetweenChars\$
- STRINGConcatenateWithSeparator, renamed to WHCombineWithSeparator\$
- STRINGLeftWord, renamed to WHLeftWord\$
- COLExists, renamed to WHColumnExists
- COLTypeAsString, renamed to WHColumnTypeAsString
- TABIsOpen, renamed to WHTableIsOpen
- CONFIGReadKey, renamed to WHConfigReadKey
- CONFIGWriteKey, renamed to WHConfigWriteKey
- STLAlterPen, renamed to WHAlterPen
- STLAlterBrush, renamed to WHAlterBrush
- STLAlterSymbol, renamed to WHAlterSymbol
- STLSymbol2Text, renamed to WHSymbol2Text
- STLBrush2Text, renamed to WHBrush2Text
- STLPen2Text, renamed to WHPen2Text
- STLText2Symbol, renamed to WHText2Symbol
- STLText2Brush, renamed to WHText2Brush
- STLText2Pen, renamed to WHText2Pen
- OBJReverse, renamed to OBJReverse
- OBJCartesianCreatePointAlong, renamed to OBJCartesianCreatePointAlong
- MAPGetExtent, renamed to WHMapGetExtent
- MAPHGetCoordinate, renamed to WHMAPGetCoordinate

- TABHRegExReplace, renamed to WHRegExReplace
- TABHRegExIsMatch, renamed to WHRegExIsMatch
- TABHRegExFirstMatch, renamed to WHRegExFirstMatch

Removed functions

- OBJDirection
- OBJDirectionWtAvg
- OBJDirectionMedian
- OBJCombineFromTable

Added functions

- WHSetCoordsysUsingMap
- WHChangeSymbolColor
- WHDebugEnabled

You can find the complete list of functions available in WindowHelper 3.7 in the chapter *Published custom MapBasic functions*.

Save Window to Workspace

The feature *Save Window to Workspace* has been reintroduced. It save the currently active window to a workspace file without saving any of the *Open Table* statements.

Group By Current Column

Group By Current Column lets you quickly get an overview over the unique values in a specific column. Was added in WindowHelper 3.6.2

Filter By Cell Value

Filter By Cell Value lets you quickly filter a column using the value in the currently selected row. Was added in WindowHelper 3.6.2

Pan and Zoom to Selection in Browser Context menu

Two menu items have been added to the context menu of the browser that lets the user pan or zoom to the selected record(s).

Hiding Base Map controls from the Open dropdowns

Via the Options dialog, you can now control which base map controls you want to hide from the three Open dropdowns.

New features in WindowHelper 3.6.0

Published functions to the MapInfo Pro interface: version 3.6 takes advantage of the new option to publish custom MapBasic functions to the MapInfo Pro interface. Currently these functions have been published:

- WINHSetCoordsysUsingTable
- STRINGReplace
- STRINGGetValueBetweenChars
- STRINGConcatenateWithSeparator
- STRINGLeftWord
- COLExists
- COLTypeAsString
- TABIsOpen
- CONFIGReadKey, CONFIGWriteKey
- STLAlterPen, STLAlterBrush, STLAlterSymbol
- STLSymbol2Text, STLBrush2Text, STLPen2Text
- STLText2Symbol, STLText2Brush, STLText2Pen

- OBJDirection
- OBJReverse
- OBJCartesianCreatePointAlong
- OBJCombineFromTable
- MAPGetExtent
- MAPHGetCoordinate
- TABHRegExReplace, TABHRegExIsMatch, TABHRegExFirstMatch

These functions will appear in the *Functions* dropdown in the *SQL Select, Label Expression, Thematic Expression* and in a number of other dialogs showing the *Functions* dropdown.

Modify Window dialog: The Modify Window dialog has been brought back on request.

New features in WindowHelper 3.5.0

Number of selected records is now shown in the statusbar. This gives you a quick overview over how many records you have selected instead of having to browse the selection.

Browse in Floating window is a new feature that lets you browse a table directly into a floating window. You can access this via the TABLE tab, via Ctrl+Shift+F4 and via the context menu of the Table List.

Static Theme lets you create a thematic that uses the values from a selected column in combination with the styles from the spatial object in the table.

New shortcuts have been added for cloning a map window via the Map Context menu of the Layer List

The state of the InfoSelHandler is now stored and restored correctly between sessions.

Dialog with functions that can used with the new Exec() function in MapInfo Pro 17.0 such as getting coordinates from a map window to be used in a SmartText.

New features in WindowHelper 3.0.0

Advanced Rename Layer is one new feature in WindowHelper. This features lets you rename a layer or cosmetic layer in a map window. You can also save this new Friendly name as the default friendly layer name for the table so that the table always will use it. And you can ask to have the table renamed in all map windows.

Rename Multiple Layers is another new feature. This lets you rename all the layers of a map to match the file name of the table. It means that the underscores of the table name can be removed with spaces.

Filter Using Cell Value lets you quickly filter the records in a browser using the cell value of the cell you right click on.

Show Info on Selection shows the attributes of the selected record in the Info window.
